

QUALITY CONTROL

MIDYEAR REPORT

Volume 17, No. 1 June 2006

INTRODUCTION

The Newborn Screening Quality Program Assurance (NSOAP), Centers for Disease Control and Prevention (CDC), distributed driedblood-spot (DBS) quality control (QC) materials for thyroxine (T_4) , thyroid-stimulating hormone (TSH), α-hydroxyprogesterone (17-OHP), total galactose (Gal), phenylalanine (Phe), leucine (Leu), methionine (Met), tyrosine (Tyr), valine (Val), citrulline (Cit), and nine acylcarnitines (C3, C4, C5, C5DC, C6, C8, C10, C14, C16) to laboratories operating newborn screening programs and to manufacturers of screening test products. Included with each semiannual shipment of OC specimens were data-report forms to be completed and returned to CDC.

This midyear report contains a summary of the QC data submitted during the first half of 2006 by state, contract, and private laboratories in the United States; international participants; and manufacturers of screening test products.

---- QC DATA ---see pages 4-25

QUALITY CONTROL MATERIALS

The QC specimen lots were provided as 6-month supplies of DBSs on filter paper. All DBS QC lots were prepared from whole blood of 55% hematocrit with lysed red blood cells. The QC materials were enriched with predetermined quantities of the selected analytes and dispensed in $100~\mu L$ aliquots on Whatman Inc. (Fairfield, NJ) Grade 903~filter paper.

A QC shipment for T₄, TSH, or 17-OHP consisted of blood-spot materials from three lots per analyte, with each lot containing a different concentration of analyte. A QC shipment for Gal, Phe, Leu, Met, Tyr, Val, Cit, and the acylcarnitines consisted of blood-spot cards from four different lots.

The QC materials were supplied for use as external controls in quantities sufficient to maintain continuity and transcend changes in production lots of routinely used method- or kit-control materials. The external QC materials were intended to supplement the participants' method- or kit-control materials at periodic intervals and to allow participants to monitor the long-term stability of their assays. The QC materials should not be used as routine daily QCs.

PARTICIPANTS' RESULTS

For this midyear report, we compiled the data that each participant reported from five analytic runs of specimens from each QC lot and calculated mean values and standard deviations from these data. Data values outside the 99% confidence interval for each OC lot were not included in the computations. We could not include qualitative data, data submitted as inequalities or ranges, data submitted in unidentified units, or data from more than five analytic runs per specimen lot per participant. Some participants submitted results in units other than those requested on the data-report forms. To ensure that all results are appropriately entered in the CDC database, participants should convert their results to the requested units before entering them on the data-report forms.

The reported QC data are summarized in tables on pages 4–25, which show the analyte by series of QC lots, the number of measurements (N), the mean values, and the standard deviations (SD) by kit or analytic method. In addition, we used a weighted linear regression analysis to examine the comparability by method of reported versus enriched concentrations. Results of the linear regression analyses are summarized in the tables on pages 4–25.

CDC/APHL

This program is cosponsored by the Centers for Disease Control and Prevention (CDC) and the Association of Public Health Laboratories (APHL).

DISCUSSION

The enriched values of the QC specimen lots, shown in the tables for each lot, do not take into account the endogenous levels of the analytes; however, analytic results indicate that endogenous concentrations are negligible for all analytes except Phe, Leu, Met, Tyr, Val, Cit, and the acylcarnitines. For Phe, Leu, Met, Tyr, Val, Cit, and the acylcarnitines, the nonenriched base pools were distributed as the first QC specimen lot in each series so that participants could measure the endogenous Phe, Leu, Met, Tyr, Val, Cit, or acylcarnitine concentration of the series. OC lots 525-528 were enriched with Gal, Phe, Leu, Met, Tyr, Val, and Cit. QC lots 565-568 were enriched with acylcarnitines. All other OC lots were enriched with one analyte per lot. Gal lots 525-528 were enriched with equimolar quantities of simple galactose and galactose-1-phosphate.

The tables, which summarize reported QC results (pages 4-25), provide data for method-related differences in analytic recoveries and method bias. Because we prepared each QC lot series from a single batch of hematocrit-adjusted, nonenriched blood, the endogenous concentration was the same for all specimens in a lot series. We calculated the withinlaboratory SD component of the total SD and used the reported QC data from multiple analytic runs for regression analyses. We calculated the Y-intercept and slope listed in each table using all analyte concentrations within a lot series (e.g., lots 511, 512, and 513). Because only three or four concentrations of QC materials are available for each analyte, a bias error in any one pool can markedly influence the slope and intercept. The Y-intercept provides one measure of the endogenous con-

centration level for an analyte. For Phe, Leu, Met, Tyr, Val, Cit, and the acylcarnitines, participants measured the endogenous concentration levels by analyzing the nonenriched QC lots. When endogenous levels were compared for the amino acids and the acylcarnitines, we found them to be similar for all methods per analyte. Ideally, the slope should be 1.0, and most slopes were close to this value, ranging from 0.8 to 1.2 but some were a bit farther away. For example, for one Gal method, the slope was 1.4; for one Leu method, the slope was 1.5; for one C14 method, the slope was 0.68; and for two C5DC methods, the slopes were 0.65 and 0.69. The C5DC methods show the greatest variation in slopes among all analytes. For C5DC, note that for both kit and non-kit users, the calculation of concentrations for the QC lots varied with type of internal standard. Data are not sorted by internal standard type. In a 2003 survey, participants reported using do-C5, d₃-C8, d₃-C10, d₃-C12, d₃-C16, or d₆-C5DC as an internal standard for C5DC. These slope deviations may be related to analytic ranges for calibration curves. Because the endogenous concentration was the same for all QC lots within a series, it should not affect the slope of the regression line among methods. Generally, slope values substantially different from 1.0 indicate that a method has an analytic bias.

Each year, with the extensive cooperation of Whatman Inc., we routinely monitor the absorption characteristics of approved filter paper. (Participants may refer to page 6 of the 2005 Newborn Screening Quality Assurance Program summary report* for charts of the serum absorbancies of 21 Grade 903 filter paper lots that CDC monitored.) The following

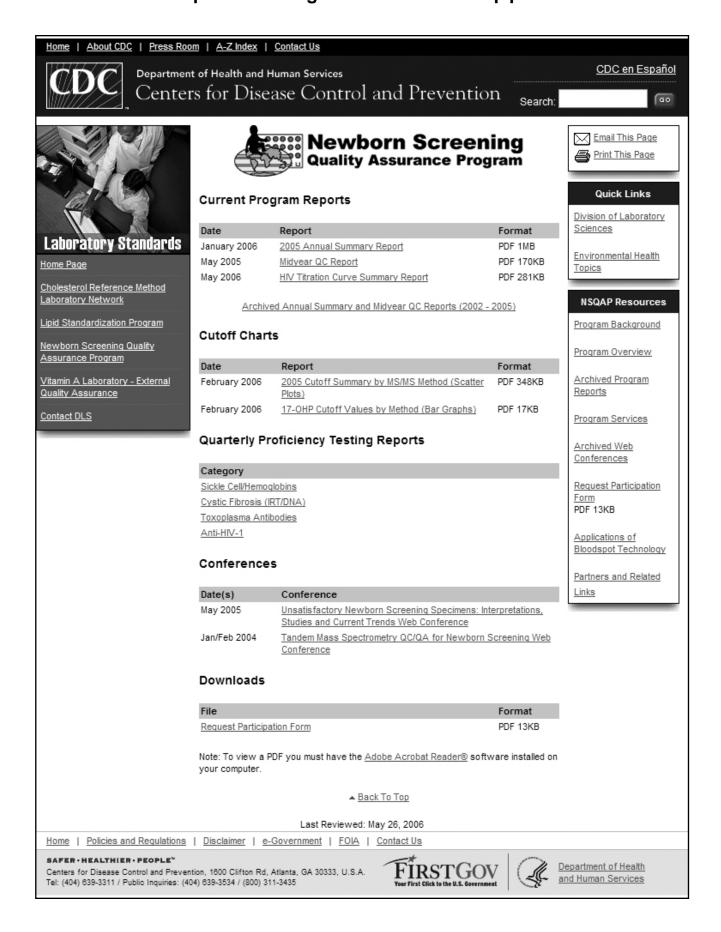

Whatman Grade 903 filter paper lots were used in the production of QC specimen lots distributed during the first 6 months of 2006: W041 (Lots 501–503, 525–528, 565–568) and W011 (Lots 451–453, 511–513).

Note that for both kit and non-kit users, the calculation of concentrations for the quality control lots varied with type of internal standard. Data are not sorted by internal standard type. In a 2003 survey, participants reported using d_9 -C5, d_3 -C10, d_3 -C12, d_3 -C16, or d_6 -C5DC as an internal standard for C5DC.

^{*}Estimated by performing a weighted linear regression analysis of mean reported concentrations versus CDC assayed concentrations and extrapolating the regression to the Y-axis.

Non-deriv MS/MS PE NeoGram	49	9.50	1.10	1.25	1.31	1.00
Lot 568 - Enriched 12 μmol/L wh	ole blood	I				
Derivatized-MS/MS Non-Kit	677	12.76	1.44	2.92	1.42	0.95
Non-derivatized MS/MS Non-Kit	49	12.53	1.15	1.20	1.31	0.94
Non-derivatized MS/MS Non-Kit Deriv-MS/MS PE NeoGram	49 179	12.53 11.33	1.15 1.30	1.20 1.57	1.31 1.18	0.94 0.84

^{*}Estimated by performing a weighted linear regression analysis of mean reported concentrations versus enriched concentrations and extrapolating the regression to the Y-axis.

NOTES

This NEWBORN SCREENING QUALITY ASSURANCE PROGRAM report is an internal publication distributed to program participants and selected program colleagues. The laboratory quality assurance program is a project cosponsored by the Centers for Disease Control and Prevention (CDC) and the Association of Public Health Laboratories.
